

⑦ Singular Value Decomposition ("SVD")

Given: data points $\{x_i\}$

Least squares: Can find line that minimizes $d_1^2 + d_2^2 + d_3^2 + d_4^2$

BUT: Only vertical distance

Sometimes that's the right thing - but not always.

What if we'd like to find a line to minimize

$$\|d_1\|^2 + \|d_2\|^2 + \|d_3\|^2 + \|d_4\|^2?$$

[Same answer as for least squares line fitting problem? No - see plc.

(Klein book: "trolley line problem")

Make problem easier (for now): Find line through origin that minimizes 2-norm distance to (\vec{x}_i) .

Mathematically: Find direction \vec{v} (assume $\|\vec{v}\|_2 = 1$) s.t.

$$\sum_i \|\vec{d}_i\|_2^2 \quad (\text{where } \vec{d}_i \perp \vec{v}, \vec{x}_i - \vec{d}_i \in \text{span}\{\vec{v}\})$$

is minimized.

(Now drop vector arrows: $x_i = \vec{x}_i$, $d_i = \vec{d}_i$, $v = \vec{v}$)

[What is d_i ? $x_i^{\perp v}$

$$x_i = x_i^{\perp v} + x_i^{\parallel v}$$

$$x_i = x_i^{\perp v} + (x_i, v)v$$

Pyth

$$\Rightarrow \|x_i\|^2 = \|x_i^{\perp v}\|^2 + \underbrace{(x_i, v)^2}_{=1} \|v\|^2$$

$$\leadsto \sum_i \|d_i\|_2^2 = \sum_i \|x_i\|^2 - (x_i, v)^2$$

want to minimize

$$= \|X\|_F^2 - \|Xv\|_2^2$$

Frobenius

← Let $X = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}$

[How do we minimize that? Maximize $\|Xv\|_2^2$.

[What's the maximal value of $\|Xv\|_2^2$? $\|X\|_2^2$

[How can we find v ? Unclear (for now). Let's assume we can.

Terminology

v : first right singular vector of $X \leadsto$ rename to v_1

$\sigma_1 := \|Xv_1\|$ first singular value of X

lec 16

review right / left singular vectors
relate to trolley line example
review quiz

Q's:

Next, assume we look for a vector $v_2 \perp v_1$ such that

$$\|Xv_2\|_2^2 \text{ is maximized.}$$

That's the second right singular vector of X .

And $\|Xv_2\|$ is the second singular value.

Next, assume we look for a vector $v_3 \perp v_1, v_2 \dots$

Then: $V^T = \begin{pmatrix} -v_1- \\ \vdots \\ -v_n- \end{pmatrix}$ if X is an $m \times n$ matrix. (assume that for now)

$\Sigma = \begin{pmatrix} \sigma_1 & & & \\ & \sigma_2 & & \\ & & \ddots & \\ & & & \sigma_n \end{pmatrix}$ where Σ is an $m \times n$ matrix in general.
 \uparrow not a sum - the Greek letter Σ .
 \swarrow same shape as X

$$X = U \Sigma V^T$$

$$\rightarrow Xv = U\Sigma \quad \text{Demo: Finding the SVD}$$

Result: The singular value decomposition factors any $m \times n$ matrix into:

$$X = U \Sigma V^T$$

where

- U is $m \times m$ orthogonal \leftarrow columns: "left singular vectors"
- Σ is diagonal, $m \times n$ and has positive entries
- V is $n \times n$ orthogonal \leftarrow columns: "right singular vectors"

Numerical example

$$A = \underbrace{\begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ 0 & -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{pmatrix}}_U \begin{pmatrix} 15 & 0 \\ 0 & 3 \\ 0 & 0 \end{pmatrix} \underbrace{\begin{pmatrix} -\frac{\sqrt{3}}{2} & \frac{1}{2} \\ \frac{1}{2} & \frac{\sqrt{3}}{2} \end{pmatrix}}_V^T$$

Pseudo inverse

Define the pseudo inverse D^+ of an $m \times n$ diagonal matrix D as

$$D^+ = \begin{pmatrix} \frac{1}{\sigma_1} & & & \\ & \frac{1}{\sigma_2} & & \\ & & \dots & \\ & & & \frac{1}{\sigma_{\min(m,n)}} \\ & & & & 0 \end{pmatrix} \quad \left. \vphantom{\begin{pmatrix} \frac{1}{\sigma_1} \\ \frac{1}{\sigma_2} \\ \dots \\ \frac{1}{\sigma_{\min(m,n)}} \\ 0 \end{pmatrix}} \right\} n$$

$$\text{for } D = \begin{pmatrix} \sigma_1 & & & 0 \\ & \sigma_2 & & \\ & & \dots & \\ & & & \sigma_n \\ 0 & & & & 0 \end{pmatrix}$$

$$D^+ = \begin{pmatrix} \frac{1}{\sigma_1} & & & \\ & \frac{1}{\sigma_2} & & \\ & & \dots & \\ & & & \frac{1}{\sigma_{\min(m,n)}} \\ & & & & 0 \end{pmatrix}$$

$$\text{for } D = \begin{pmatrix} \sigma_1 & & & \\ & \sigma_2 & & \\ & & \dots & \\ & & & \sigma_n \\ & & & & \sigma \end{pmatrix}$$

[What to do about zero (or near-zero) σ_i ? leave them as 0

Then define the pseudo inverse A^+ of a general matrix A by its SVD.
If $A = U \Sigma V^T$, then define $A^+ = V \Sigma^+ U^T$.

[Pseudo inverse of example?

Q's: eigenvalues of A = eigenvalues of A^T ?

Applications of the SVD

① Least squares problems

Fact: A^+b solves the least squares problem $\min_x \|Ax - b\|_2$

This generalizes our QR-based method. \rightarrow HW

[How? By also allowing underdetermined systems. (Fewer eqns than unknowns, $A = \begin{matrix} \text{fat} \\ \text{short} \end{matrix}$)

② Principal component analysis \rightarrow HW3

③ Computing $\|A\|_2$ $\|A\|_2 = \sigma_1$

④ Computing the 2-norm condition number

Assume A invertible.

Recall: $\kappa(A) = \|A\| \|A^{-1}\| = \sigma_1 / \sigma_n$

$$A = \left(\begin{array}{|c|} \hline \|u\| \\ \hline \end{array} \right) \begin{pmatrix} \sigma_1 & & \\ & \ddots & \\ & & \sigma_n \end{pmatrix} \left(\begin{array}{|c|} \hline \|v^T\| \\ \hline \end{array} \right) \quad A^{-1} = \left(\begin{array}{|c|} \hline \|v\| \\ \hline \end{array} \right) \begin{pmatrix} \sigma_1^{-1} & & \\ & \ddots & \\ & & \sigma_n^{-1} \end{pmatrix} \left(\begin{array}{|c|} \hline \|u^T\| \\ \hline \end{array} \right)$$

$\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_n \geq 0$

Now, for any matrix (not just square/invertible), it turns out that

σ_1 / σ_n is the condition number.

(And that's also how it's computed. — Quite expensive!)

⑤ Low-rank approximation

$$A = \left(\begin{array}{c|c|c|c|} \hline | & | & | & | \\ \hline u_1 & u_2 & \dots & u_n \\ \hline \end{array} \right) \begin{pmatrix} \sigma_1 & & & \\ & \sigma_2 & & \\ & & \dots & \\ & & & \sigma_n \end{pmatrix} \begin{pmatrix} \hline \hline v_1^T \\ \hline \hline \end{pmatrix}$$

sum of outer products
= sum of rank-1 matrices
of decreasing norm!

$$= \begin{pmatrix} | & | & & | \\ u_1 & u_2 & \dots & u_n \\ | & | & & | \end{pmatrix} \begin{pmatrix} \hline \sigma_1 v_1^T \\ \hline \sigma_2 v_2^T \\ \hline \dots \\ \hline \sigma_n v_n^T \\ \hline \end{pmatrix} \leftarrow \sigma_1 u_1 v_1^T + \sigma_2 u_2 v_2^T + \dots + \sigma_n u_n v_n^T$$

Idea: Could just use first few as an approximation.

In fact: $\sum_{i=1}^k \sigma_i u_i v_i^T$ is the closest rank- k matrix to A
(measured in the Frobenius-norm.)

Demo: image compression

[What happens if rank $A \leq k$? $A = \sum_i^k \sigma_i u_i v_i^T!$

[How does this relate to the trolley line problem? Closest rank-1!

Original trolley line problem:

Line through the origin

More generally - how about:

Line not through origin?

Just need one point on that line:
Can then subtract that point from all data.

Fact: $\frac{1}{n} \sum_{i=1}^n x_i$ is such a point.

[Relationship to PCA?

↳ "centroid"

Q:

Can define a variant of the SVD where U, V are not square.

"thin" SVD

[Why is this important?

U consumes a large amount of memory.
